Need for a Community Model Inter-Comparison: Complexity *versus* Simplicity

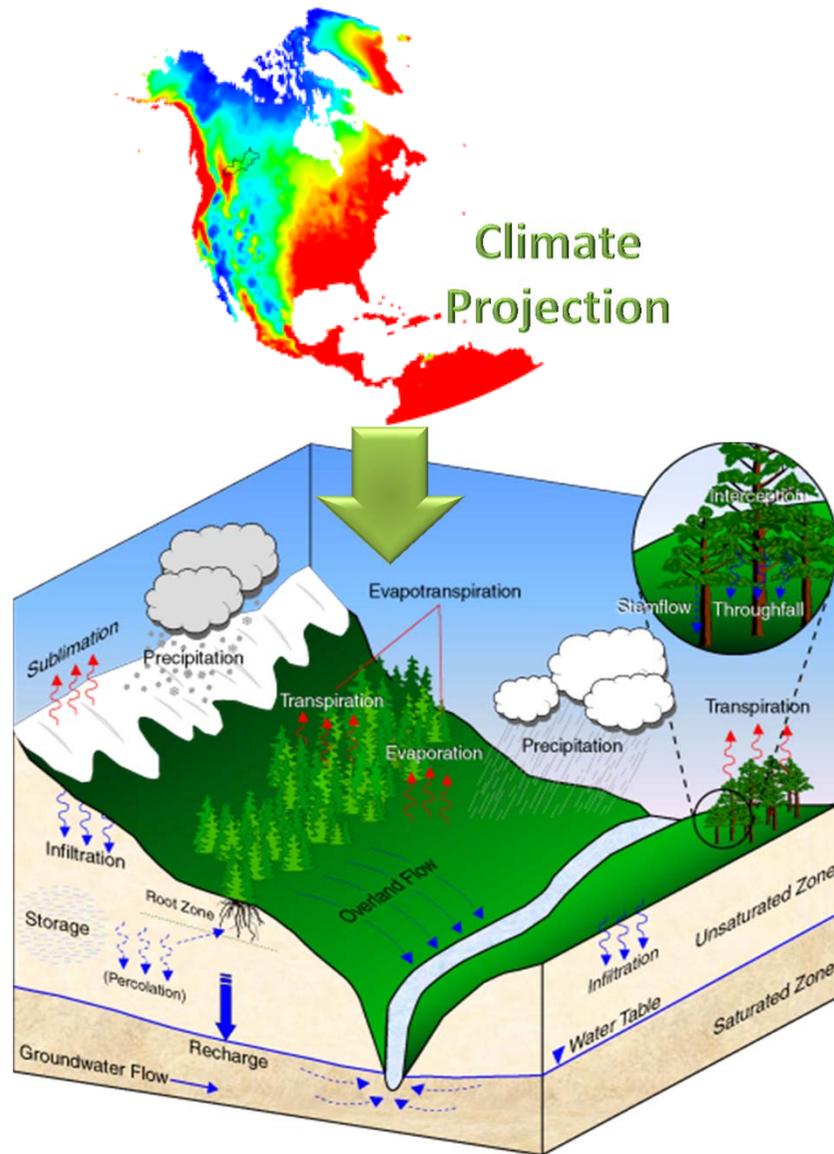

- Many models – some comprehensive, some less so
- Some physics-based (i.e., coupled PDE's), some “lumped”
- Some structured, some “cobbled” together
- Some flexible, some “rigid”
- Disparate data needs
- Avoid “model wars”

A community model inter-comparison...

- Could use well-characterized data-rich watersheds as a platform
- Include models ranging from comprehensive (complex?) to simple (parsimonious?)
- Water quantity, water quality
- Not a competition to define winners and losers
- Serves the entire hydrologic community (scientific, consulting, government, regulatory, policy sectors)

HydroGeoSphere Philosophy

HGSTM
SIMULATION

- Fully-coupled 3D model based on PDEs to capture interactions between surface and subsurface water flow, solute and energy transport
- Can be “simplified” to consider only individual water cycle components

Examples of Coupled Surface-Subsurface Models

Earliest known coupled surface/subsurface flow model:
Freeze, R.A. and R.L. Harlon, Blueprint for a physically-based, digitally-simulated hydrologic response model, *J. Hydrol.*, 9, 237-258, 1969.

Some Existing “*Integrated*” Models:

- InHm
- HydroGeoSphere
- MODHMS
- Parflow
- OpenGeoSys
- CATHY
- PIHM
- ...

Seems to be a growing area of model development, but do we need more models, or more applications centered on resolving key societal concerns & scientific questions ?

Overview of “HydroGeoSphere” Model Features

- 2D overland/stream flow (Diffusion-wave equation), including stream/surface drainage network genesis;
- 3D variably-saturated flow (Richards’ equation + ET) in porous medium;
- 3D variably-saturated flow in macropores, fractures and karst conduits (dual-porosity, dual-permeability or discrete fractures);
- Advective-dispersive, reactive solute/thermal transport in all continua, snow accumulation/melting, soil freeze/thaw;
- Groundwater age, life expectancy
- Allows for complex topography, irregular surface & subsurface properties, density-dependent flow, subgridding & subtiming
- Fully-coupled, simultaneous solution of surface/subsurface flow and transport via Control-Volume Finite Element or Finite Difference Methods.

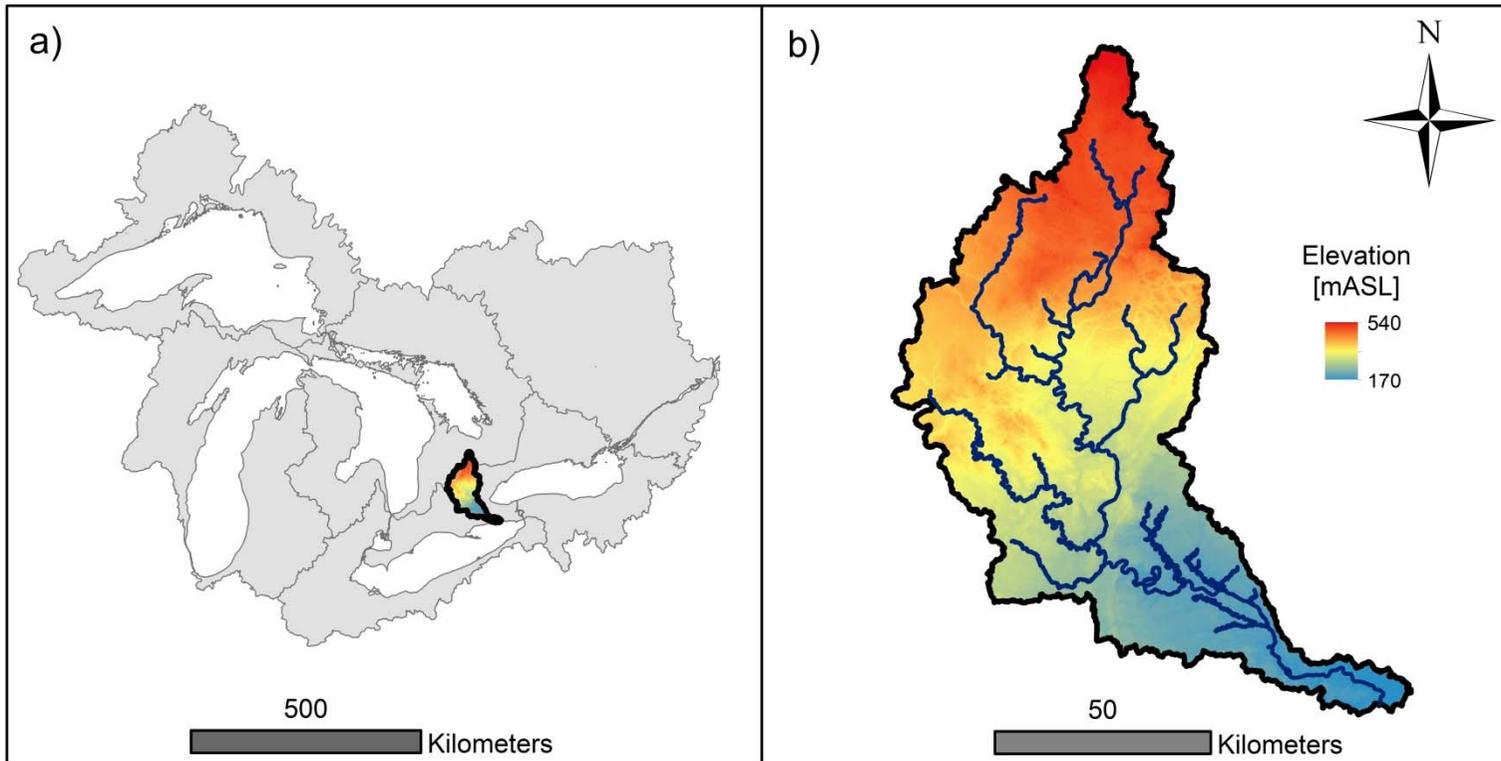

Grand River Watershed Background

- 7000 km²
- Population of ~900,000
- Intensive Agriculture
 - 93% rural/agricultural land use
 - 290,000 head of cattle
 - 500,000 thousand swine
 - 8.8 million poultry
- 900 mm of precipitation/year
- Heavy Dependence on Groundwater for Municipal Water Supply
- Well Instrumented
- Long Term Records

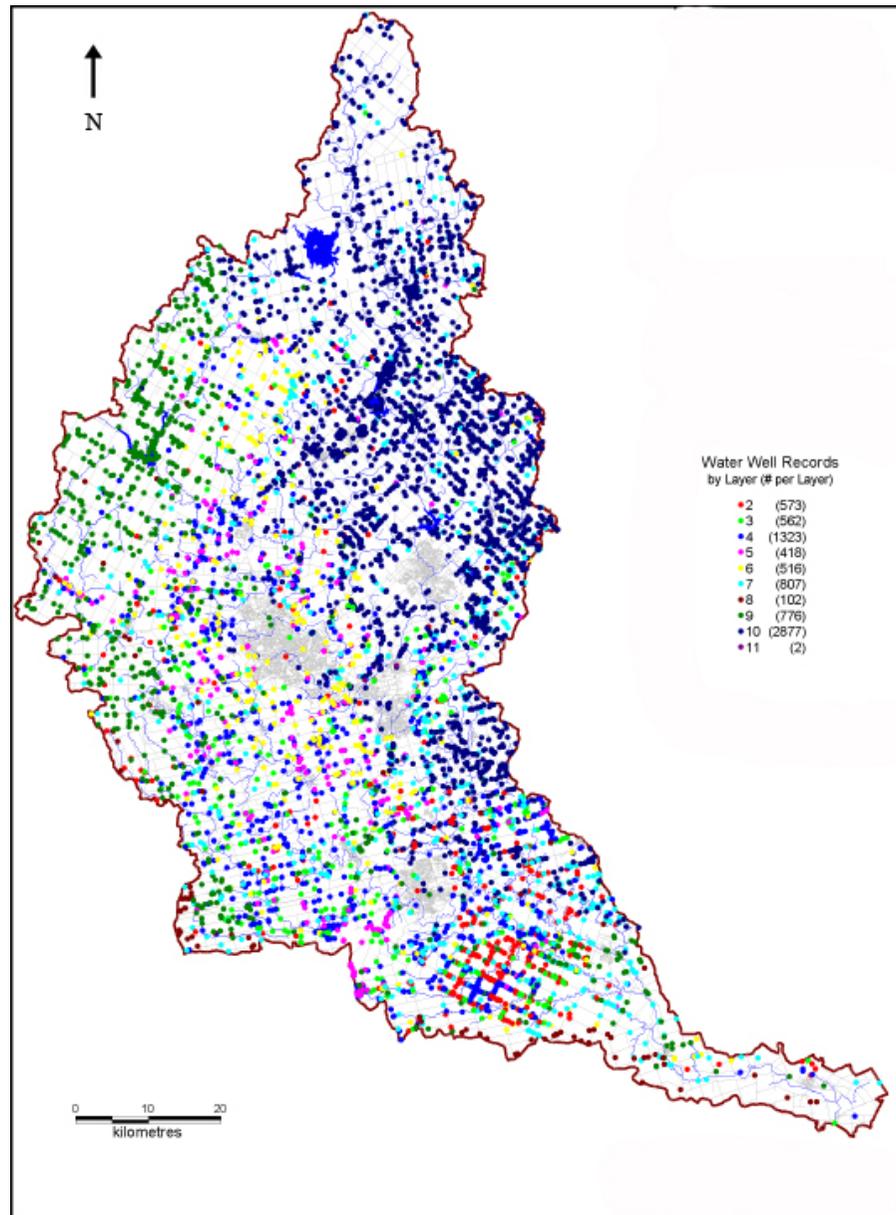

Location Within Great Lakes Basin

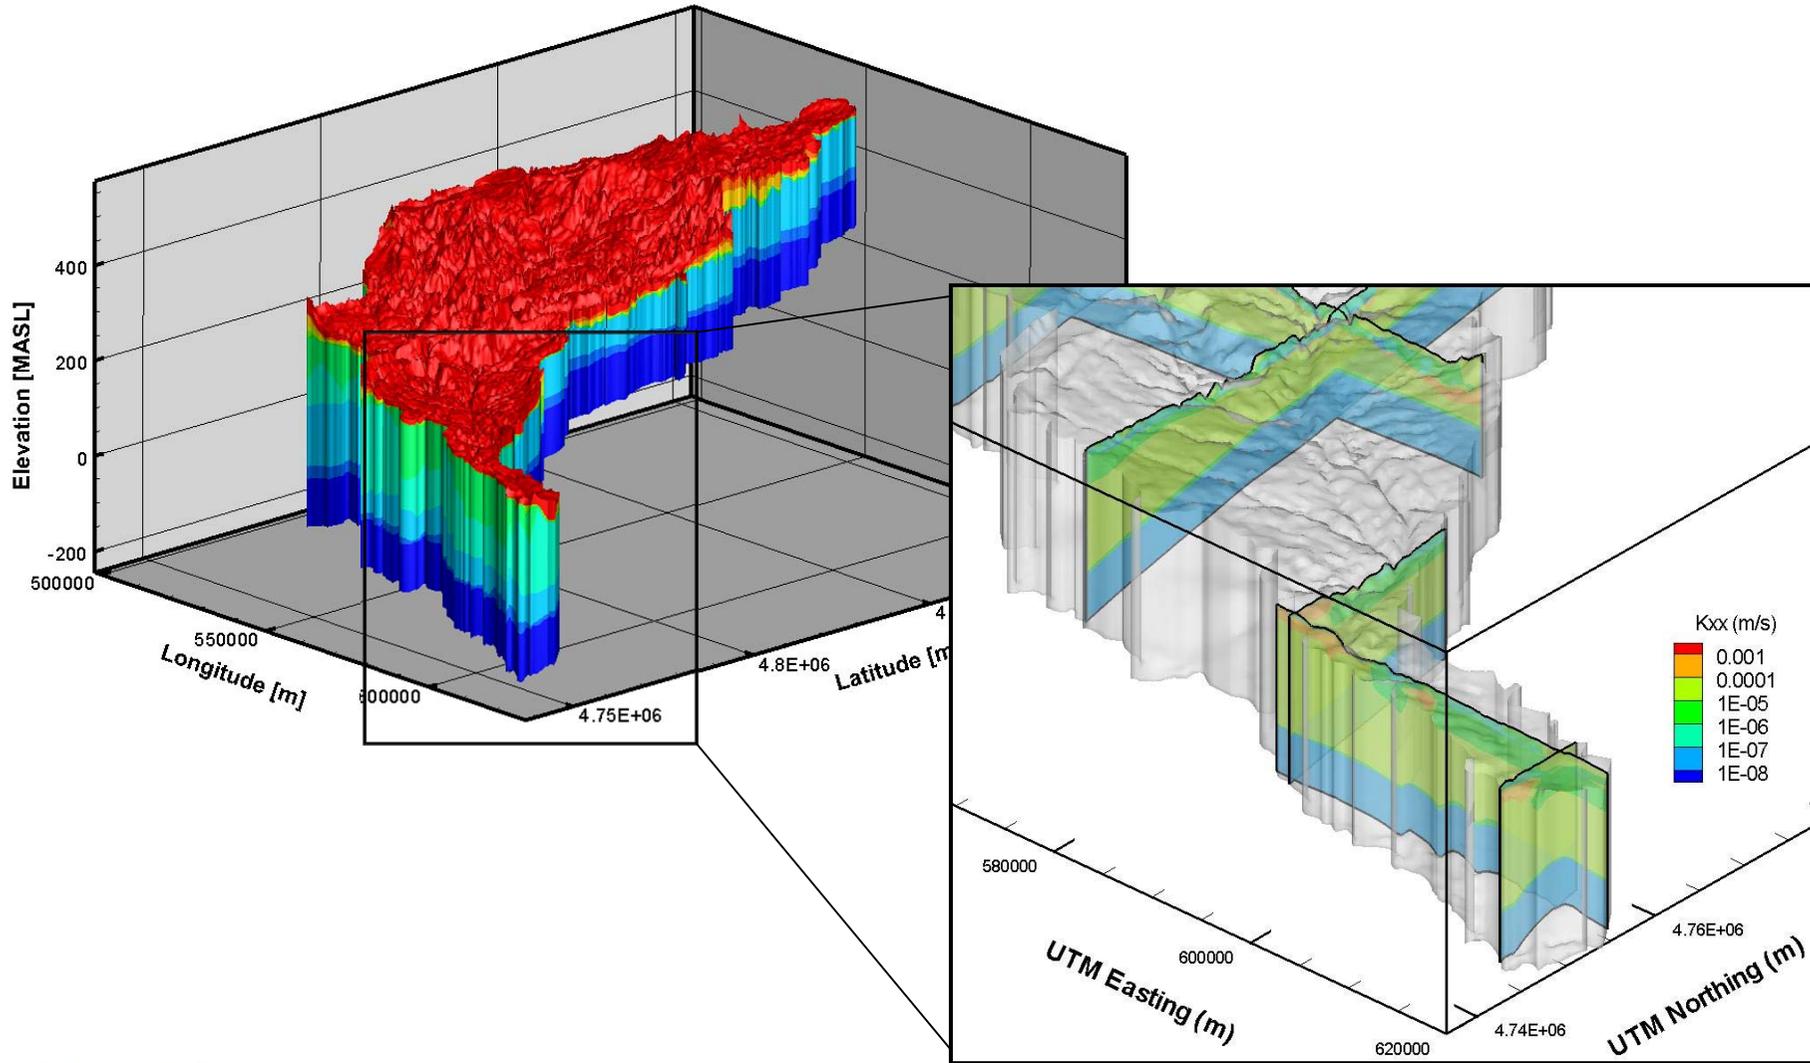

Drilling and Water Well Records

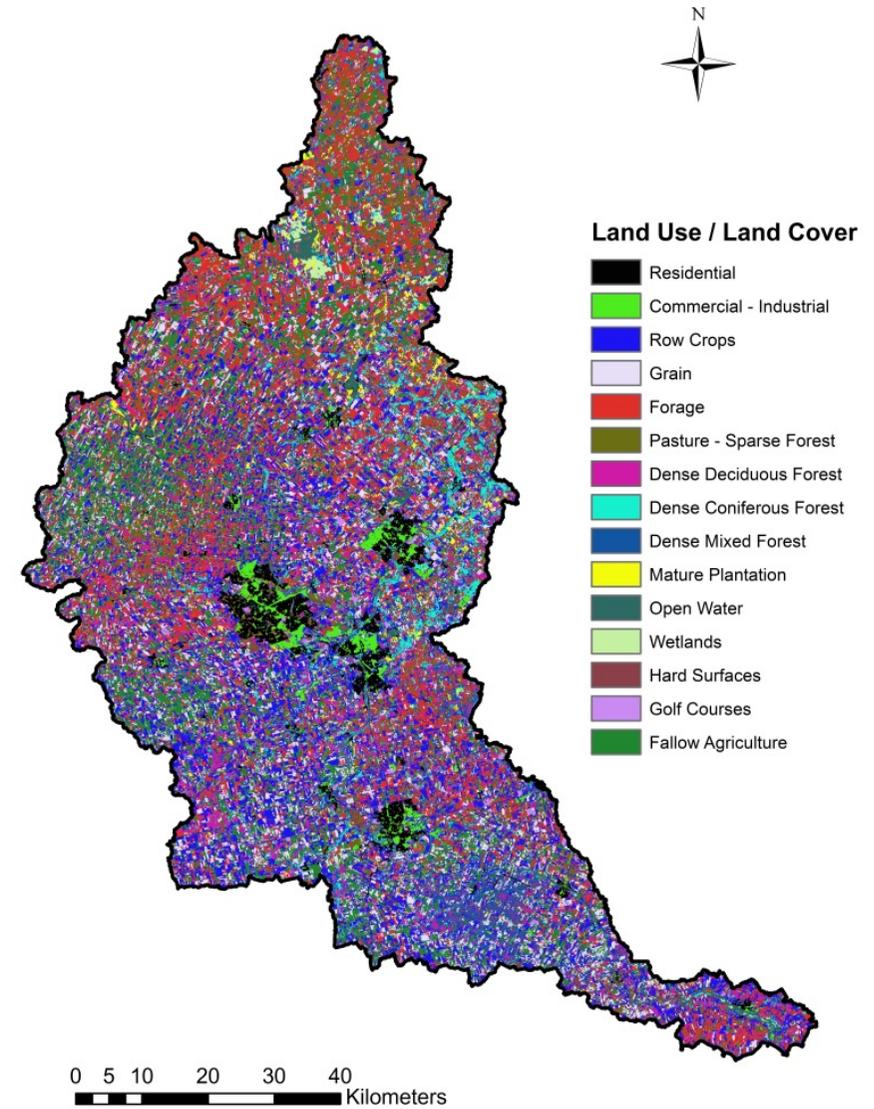

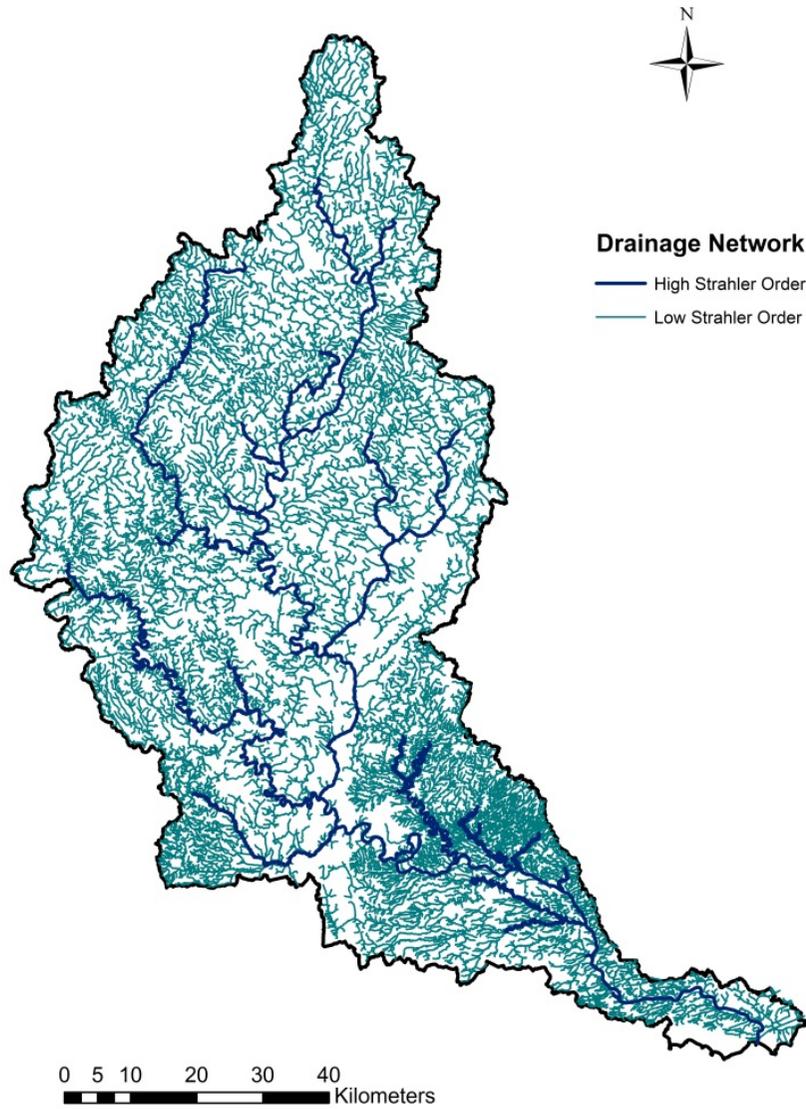

3D Geological Model

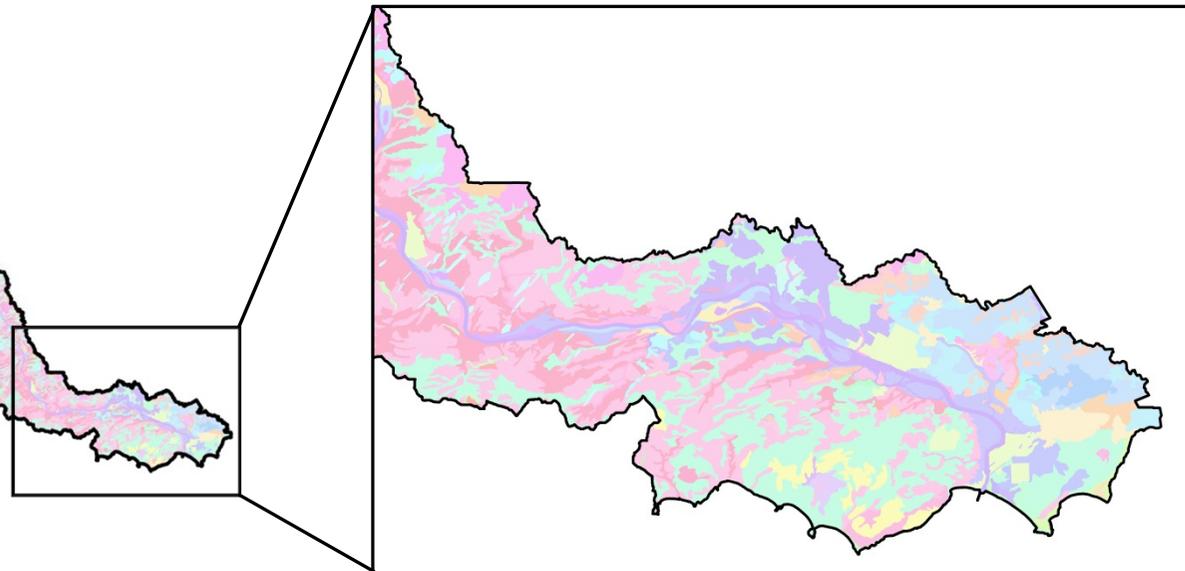

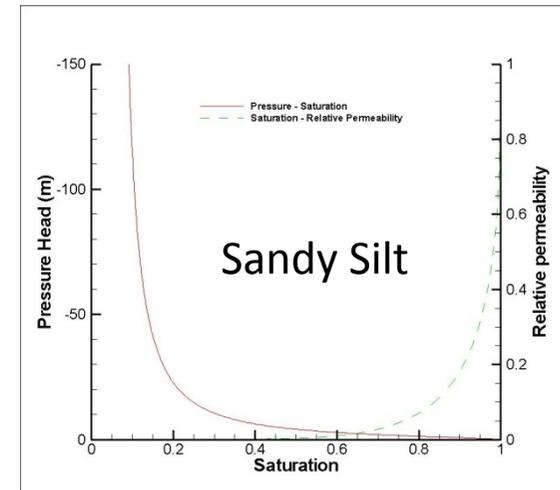

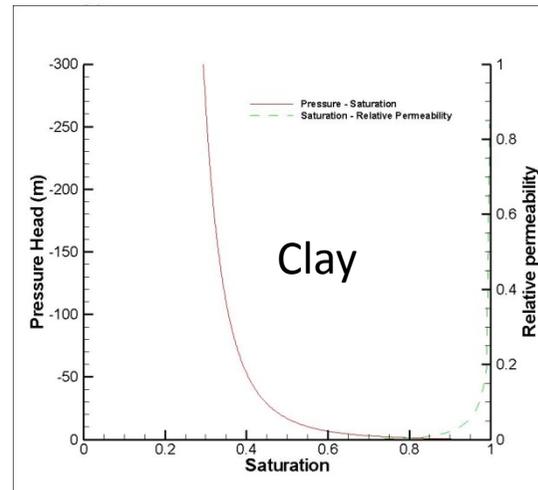

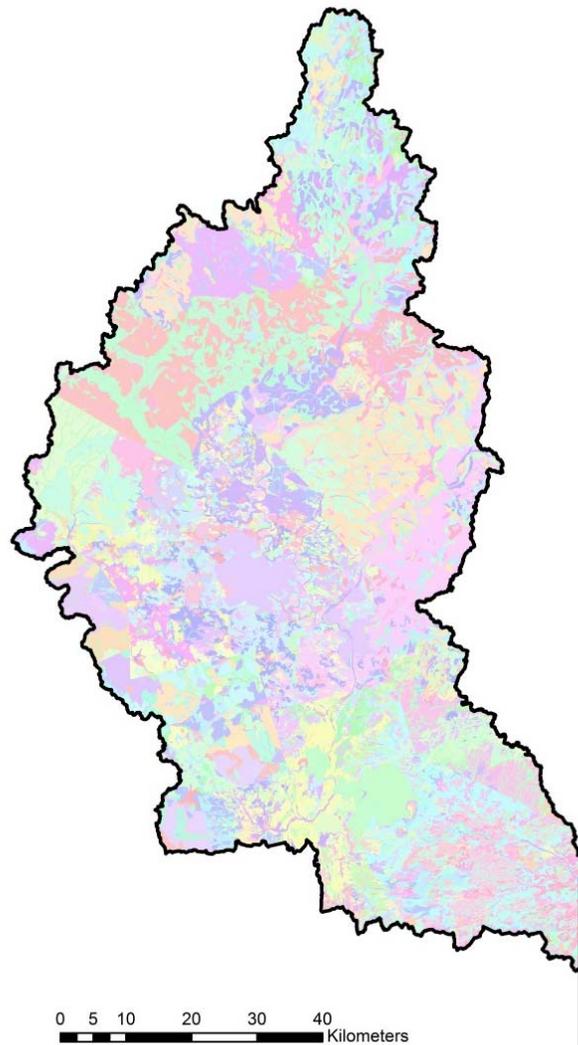

Extensively Characterized

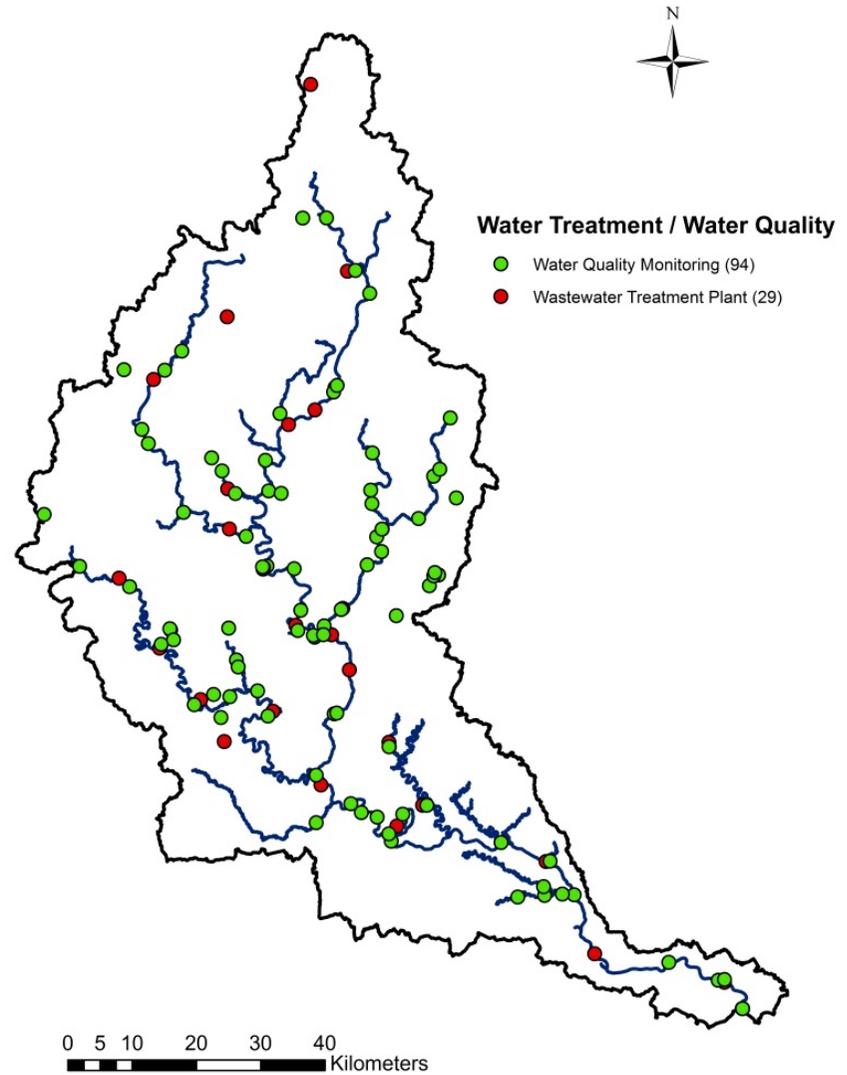

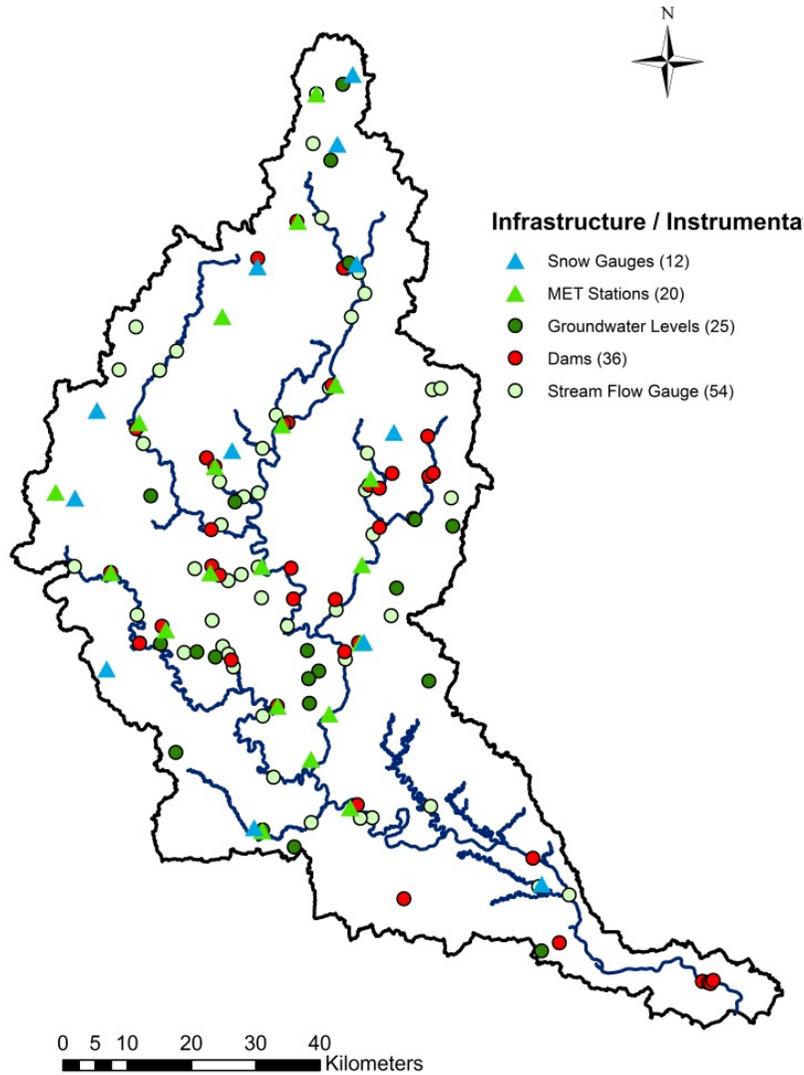

Well Defined Soil Type Distributions

Extensively Monitored

Water Budget

Water Budget Parameter	Value (mm/year)
Precipitation	930
Evapotranspiration	605
Surface Flow Out of GRW	313.5
Infiltration	465
Exfiltration	170
Recharge	186
Groundwater Flow Out of GRW	0
Groundwater Pumping	11.5

Smart Watershed Monitoring

Making the Grand River Watershed “Smarter”

Why the Grand River?

Why the Grand River? It's an urbanizing watershed with a unique mix of pristine, urbanizing, urban and agricultural land uses making it a perfect place for research and development.

In collaboration with IBM, the Southern Ontario Water Consortium has built a system that allows them to collect, store and analyze data from sensors in the Grand River Watershed in Southern Ontario.

Grand River Facts

The Grand River is the largest inland river system in southern Ontario supplying water to the Region of Waterloo, Brantford and Six Nations.

The Grand River comprises

of the Canadian land area draining into Lake Erie and is approximately

300km

long with 750,000 people living within its watershed.

Platform Facts

The platform analyzes data collected every 15 minutes from meteorological, surface, subsurface and groundwater sensors, which monitor everything from rain- and snowfall, soil moisture, water turbidity, flow rates, temperature, to ground- and well-water quality.

600 data points per hour

streaming from more than

120 sensors

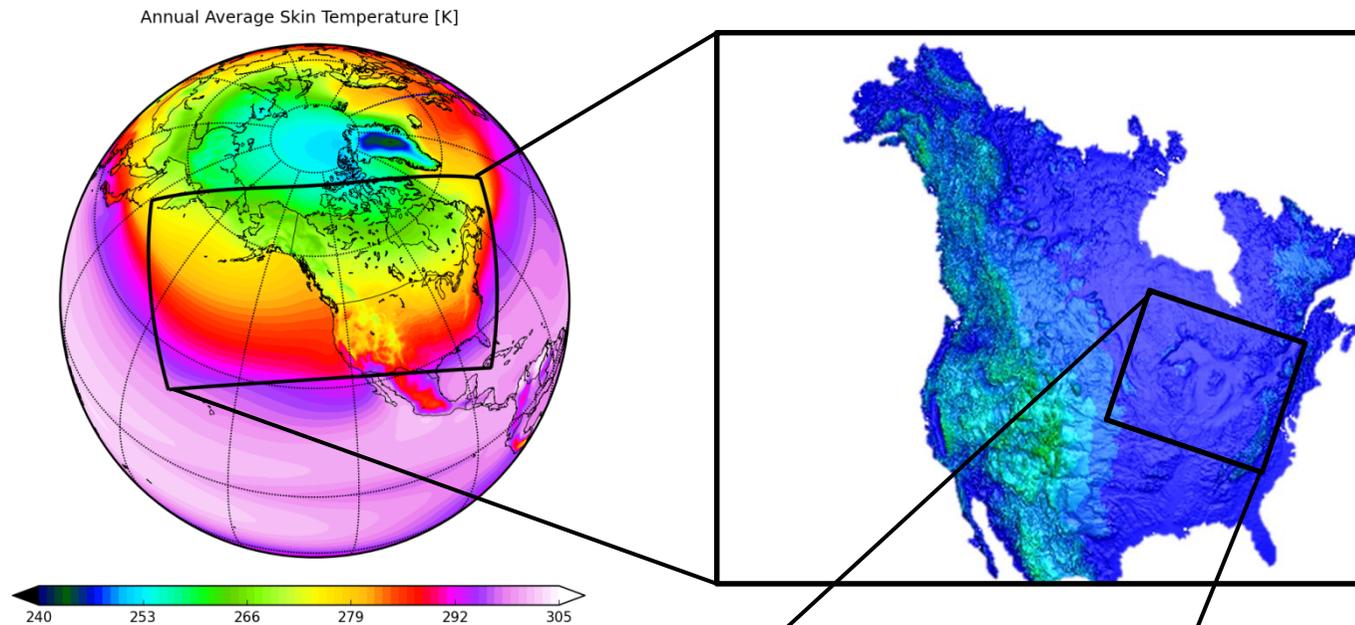

installed within 80 square kilometers of watershed that nourishes urban, agriculture and forested land along the Grand River.

Climate Projections (Peltier et al., U of T)

Dynamical Downscaling of Climate: CESM & WRF

CESM (GCM):
~ 80km resolution

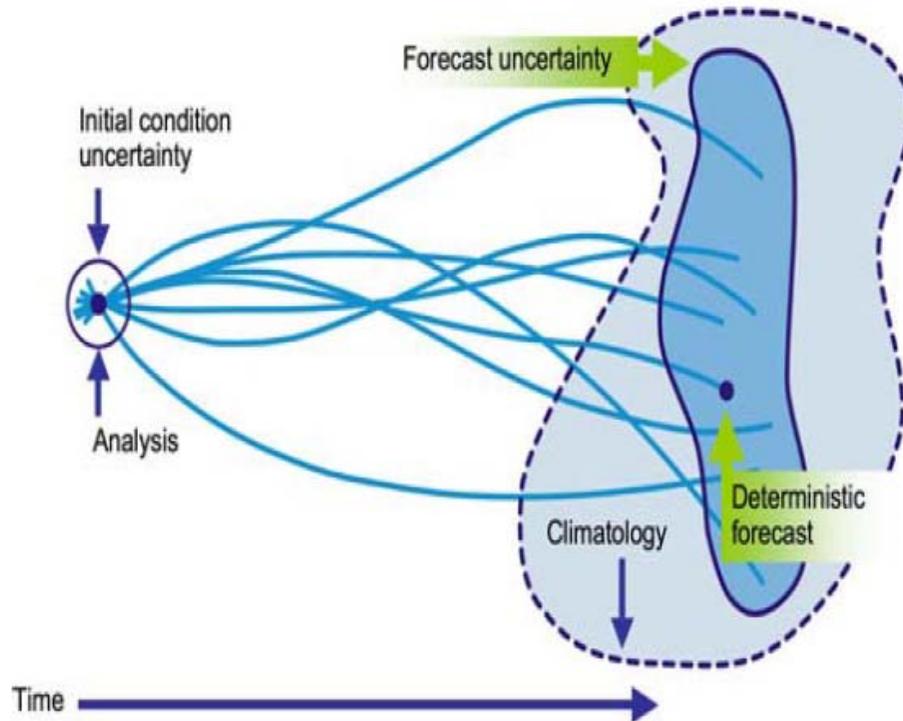

WRF (RCM):

- 30km resolution for North America
- 10km resolution for Great Lakes Basin
- 6 hourly forcing

Background – Climate Projections

Initial conditions and uncertainty

A conceptual model of climate projection: all trajectories begin in a reasonably well defined initial state, they then spread and decorrelate with time to arrive at a random location within a new but equally well defined distribution

Climate is essentially the statistical average of the weather in a particular region over a particular time window.

- Climate change is a shift in these statistical characteristics with time

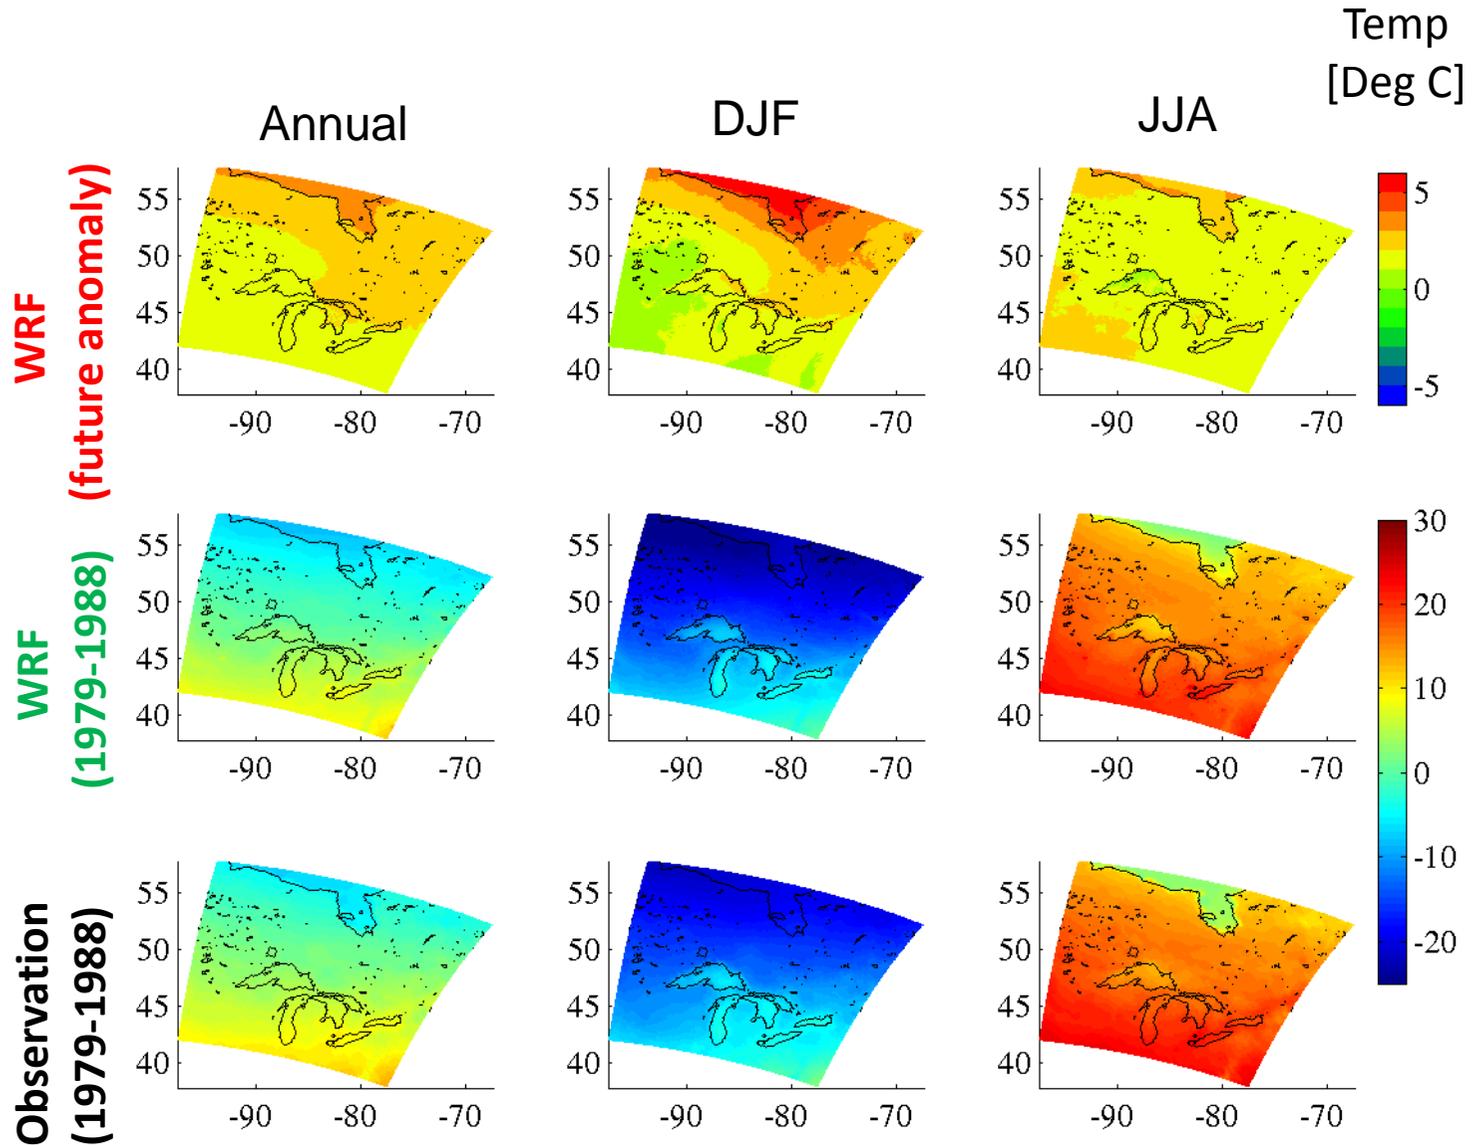

Even though we cannot predict individual weather events we can predict (project) changes in the nature of their statistical distribution

Observation vs. WRF vs. Future (2045-2054)

WRF 10kms
10 years avg

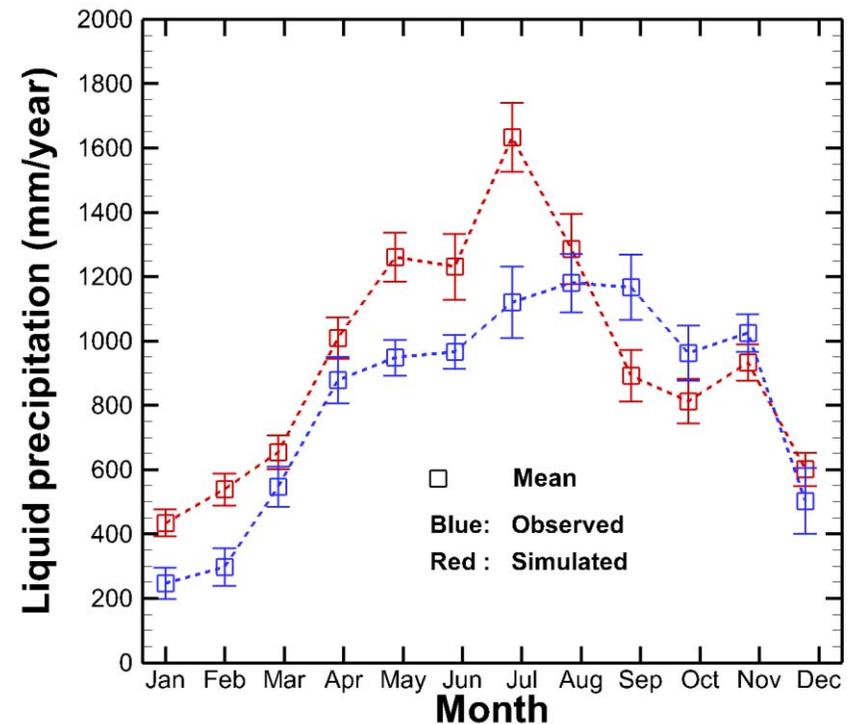

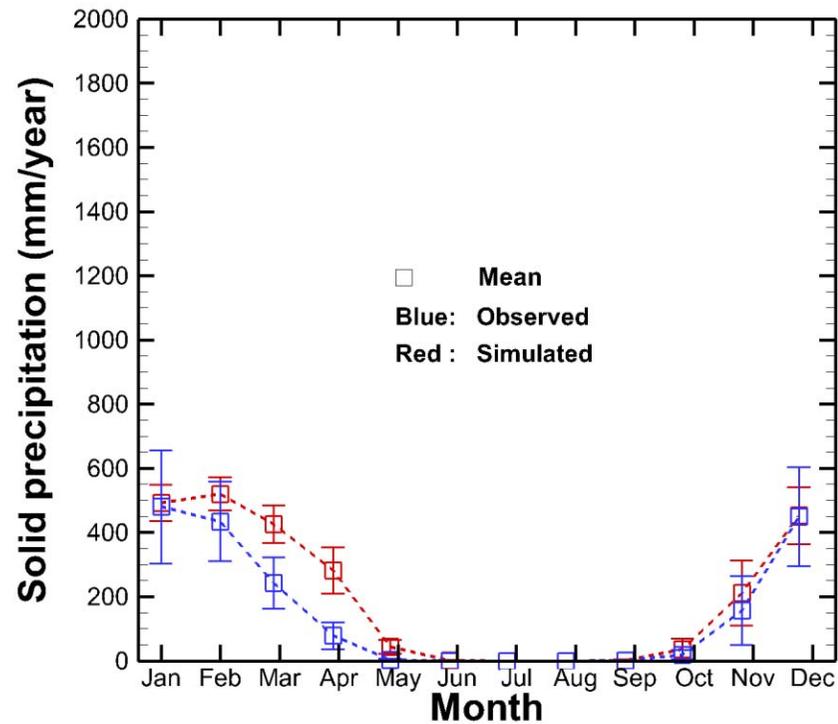

Compared to the
NARR dataset

Integrated Models: Our Lessons from Experience

- Integrated models showing promise in characterizing hydrologic cycle processes at multiple scales in watersheds.
- Parameterization: There is always “missing” data.
- Computational challenges remain, but with modern numerical solution methods, parallel computing & HPC’s, there is optimism for handling very large complex systems.
- Fully integrated solution is robust and provides a holistic view of water, contaminant & heat transport .
